HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Radiation-induced neurotoxicity assessed by spatio-temporal modelling combined with artificial intelligence after brain radiotherapy: the RADIO-AIDE project

Context

- **High-grade glioma**: The most frequent high-grade brain tumor in adults
- **Radiotherapy (RT)**: One of the most important treatments, generally combined with surgery and/or chemotherapy
  - Increased patient survival;
  - But increase of side effects like cognitive impairments (ex: attentional, executive and memory disorders) => Altered quality of life for patients.
- **Potential toxicity of RT on the central nervous system?**
  - Which neurotoxic mechanisms are potentially associated with the initiation and progression of post-RT brain lesions?
  - Are there spatio-temporal (ST) signatures of these post-RT brain lesions?
  - Could these post-RT brain lesions be associated with the initiation and temporal progression of cognitive impairments?
  - What about the radio sensitivity of the brain structures implied in cognitive processes?

Objectives

The RADIO-AIDE project is a multidisciplinary project of 4 years, that started in April 2022.

- **Clinical objective**: To generate new knowledge about the neurotoxic mechanisms implied in the initiation and temporal progression of cognitive impairments following brain RT
- **Methodological objectives**:
  - To provide to clinicians a usable academic software to perform an automated longitudinal extraction of clinically relevant image-based biomarkers from brain magnetic resonance images (MRI) acquired in clinical routine;
  - To develop artificial intelligence (AI) tools to predict individual cognitive impairments at early stage after brain RT

EpiBrainRad cohort

<table>
<thead>
<tr>
<th>Number of patients included</th>
<th>AP-HP Pitié Salpêtrière</th>
<th>ICANS</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>172</td>
<td>71</td>
<td>243</td>
<td>100%</td>
</tr>
</tbody>
</table>

Deceased patients

- Total number of MRIs (Average per individual; Max)
  - 1779 (10; 29)
- Number of patients with at least 3 MRIs
  - 160
- Number of MRIs per patient with at least 3 MRIs scan
  - 1761 (11; 29)
- Number of patients with neuropsychological exams at baseline (BL) and at 12 months
  - 64

- at BL and at 12 months
  - 22
- at BL, 12, 24 and 36 months
  - 10

Results and perspectives

- An extension of the EpiBrainRad cohort is in progress. New patients will be included from 2023.
- An annotated dataset including ground truth labels for post-RT WMH, vascular lesions and tumoral lesions as well as many brain regions of interest implied in cognitive functions is being produced from the brain MRIs of the EpiBrainRad cohort. This large and well curated learning data set will feed the ST models and AI tools subsequently developed.
